

# CS 1340:Fall 2020:Lecture 08

Intro to Python for CS and Data Science

---

Mark Fontenot, PhD

Southern Methodist University

## Types - The Highlights

---

A great additional resource to understanding them: [Python Dictionaries 101: A Detailed Visual Introduction](#)

## Write Some Code

```
# What's the average age of all the friends?  
friends = {  
    'Bob': 19,  
    'Sally': 20,  
    'Muhammad': 18  
}
```

## File Input

---

## Let's Make a Text File

---

## Let's Make a Text File

- Right click in the Project Explorer (VS Code)
- Choose New File
- Type a name and hit enter/return
- Type your three favorite colors in the file, each on a separate line

## Reading From a File

- right-click on the file you created and choose copy path.
- store the path in a variable
- open the file

```
file_path = '/Users/mark/Code/cs1340-f2020/lectures-drafting/abc.test'  
color_file = open(file_path, 'r')
```

- r means reading
- w means writing
- x means creating and writing to a new file

```
# Continuing from the previous slide
```

```
color01 = color_file.readLine()
```

```
color02 = color_file.readLine()
```

```
color03 = color_file.readLine()
```

- **string literal** - 'SMU'
  - something enclosed in quotes
- **sequence type** - an ordered collection of items
  - 'SMU' is really like S M U
  - The position in the sequence is called the **index**
  - **Indexes** start at 0

(you know this already, but ...)

```
school_mascot = 'Peruna'  
print (school_mascot)  
print ('school_mascot')
```

Peruna

school\_mascot

- You can find the length of a *sequence* by using the `len()` function

```
school_mascot = 'Peruna'  
print(len(school_mascot))
```

6

- String Concatenation

```
f_name = 'Mark'
```

```
l_name = 'Fontenot'
```

```
full_name = f_name + ' ' + l_name
```

(as we saw last week...)

- you cannot directly modify a string
  - you have to create a new string with what you want
  - ... just a reminder

## Lists - 1

- **list** - a container that stores related values together
- created using square brackets []

```
universities = ['smu', 'tcu', 'utd', 'uta']  
for school in universities:  
    print (school)
```

```
smu  
tcu  
utd  
uta
```
